

Announcements and the Role of Policy Guidance

Carl E. Walsh*

This draft: December 18, 2007

Abstract

By providing guidance about future economic developments, central banks can affect private sector expectations and decisions. This can improve welfare by reducing the effects of asymmetric information and by leading to smaller forecast errors. But it can also magnify the impact of noise in the central bank's forecasts. I employ a model of heterogeneous information to compare outcomes under opaque and transparency policies. While *better* central bank information is always welfare improving, *more* central bank information may not be.

1 Introduction

Standard models used for monetary policy analysis typically assume private agents and the central bank share a common information set and economic model, yet actual policy decisions are taken in an environment in which asymmetric information is the norm and many alternative models coexist. The resulting heterogeneity in views can play an important role in affecting both policy choices and the monetary transmission process. Transparency in the conduct of policy can help to reduce asymmetric information. Inflation targeting central banks, for example, invest significantly in attempting to reduce uncertainty about the objectives of policy, while the release of detailed inflation and output projections can serve to ensure the public shares the central bank's information about future economy developments. By being

*Professor of Economics, University of California, Santa Cruz (walshc@ucsc.edu) and Visiting Scholar, Federal Reserve Bank of San Francisco. Prepared for the 32nd Annual Economic Policy Conference, Federal Reserve Bank of St. Louis Conference, October 19-20, 2007. Any views expressed are not necessarily those of the Federal Reserve Bank of San Francisco or the Federal Reserve System.

transparency about its objectives and its outlook for the economy, central banks help provide the public with guidance about the future.

But providing guidance carries with it risks. As Poole (2005) has expressed it,

...for me the issue is whether under normal and routine circumstances forward guidance will convey information or whether it will create additional uncertainty.

Since any forecast released by the central bank is subject to error, being more transparent may simply lead private agents to react to what was, in retrospect, noise in the forecast. The possibility that the private sector may overreact to central bank announcements does capture a concern expressed by some policy makers. For example, in discussing the release of FOMC minutes, Janet Yellen expressed the view that “Financial markets could misinterpret and overreact to the minutes” (Yellen 2005).

In this paper, I explore the role of economic transparency – specifically, transparency about the central bank’s assessment of future economic conditions – in altering the effectiveness of monetary policy. I do so in a framework in which central bank projections may convey useful information but may also introduce inefficient fluctuations into the economy.

A focus on economic transparency seems appropriate for understanding the issues facing many central banks. The recent concerns about the implications of the subprime mortgage market reflect, in part, private sector uncertainty about the Fed’s view of the economic outlook and the way the outlook for inflation and real economic activity may be affected by financial market conditions. Throughout 2007, for example, many financial market participants appeared to hold more pessimistic views than the Federal Reserve about future economic developments,¹ and in recent months, market participants have often expected significant interest rate cuts, while some members of the FOMC have emphasized concerns about the outlook for inflation, suggesting they saw less need for rate reductions.² News reports speculating on possible interest rate cuts by the Fed or the ECB focused very

¹ “Even as Wall Street analysts ratchet up their worries about a recession, Fed officials are from from convinced that a true downturn is likely.” New York Times, September 8, 2007. A more vivid example of disagreement was provided by CNBC commentator Jim Cramer, whose blast at the Fed as clueless about “how bad it is out there” was reportedly seen by more than a million viewers on YouTube.

² At its meeting on December 11, the Fed cut its fed funds rate target by 25 basis points, disappointing financial markets and leading to a decline of almost 300 points in the Dow Jones the next day.

little on uncertainty about the central bank's preferences but a great deal on the uncertainty about the outlook for the economy. These reports reveal heterogeneity among private forecasters and uncertainty about the Fed's (or the ECB's) outlook for the economy. And public statements by central bankers were designed to communicate their views on future economic developments. From Jean-Claude Trichet's statement that the markets "have gone progressively back to normal" (quoted in the *Financial Times*, August 15, 2007, page 1) to Ben Bernanke's comment that housing remains a "significant drag" on the economy (speech at the NY Economic Club, Oct. 15, 2007), central bankers signal their assessment of economic conditions, and this assessment is one factor that influences the (heterogeneous) outlooks among the private sector.

The uncertainty in financial markets in recent months illustrates clearly the significant differences that can arise between the central bank and private market participants. This is a classic example of asymmetric information about the economy. Much of the debate has been focused on the question of future interest rate cuts, but the underlying issues appear to be related to differing views among private forecasters and between private forecasters and the Fed over the likely impact of financial market disturbances on the real economy and the likelihood of a future recession.

The next section discusses the two goals of transparency Bill Poole (2005) has stressed – accountability and policy effectiveness. Then, section 3 develops a model of asymmetric and heterogeneous economic information that can be used to model the implications of transparency. Two policy regimes are considered. In the first, the public observes the central bank's instrument choice, but the central bank provides no further information to the public. In the second, the central bank provides information on its outlook for future economic developments. The welfare implications of these regimes are discussed in section 4. Within each regime, better *quality* central bank information is always welfare improving (the pro-transparency aspect of Morris and Shin 2002 emphasized by Svensson 2006). However, across regimes, *more* central bank information has ambiguous effects. Section 5 concludes.

2 The goals of transparency

Transparency requires asymmetric information, but the nature of this asymmetry can take many forms. In fact, Geraats (2002) has classified five types of transparency – political, procedural, economic, policy, and operational.

Briefly, these correspond to transparency about objectives, the internal decision making process, the central bank's forecasts and models, the central bank's communications about its policy actions, and its instrument setting and control errors. Each of these dimensions of transparency are important and have been studied extensively (see Geraats 2002 for a survey),

In recent years, central banks have become more transparency along all these dimensions, and levels of transparency that would have been viewed as exceptional twenty years ago are today accepted as best practice among modern central banks.³ The trend towards central bank independence with explicit mandates assigned to central banks and the wide-spread adoption of inflation targeting has contributed greatly to political transparency. The Bank of England is among the most procedurally transparent central banks, publishing minutes and individual votes of its Monetary Policy Committee discussions. Central banks such as the Federal Reserve that were formerly reluctant to communicate policy actions directly now do so clearly, timely, and directly. The most transparent central banks, such as the Reserve Bank of New Zealand and the Bank of Norway, publish their projections for the policy interest rate. The use of a short-term interest rate as the instrument of policy has greatly enhanced operational transparency. But while most central banks today are transparency about their policy stance and operational procedures – something hard to avoid when using a short-term market interest rate as the instrument of policy – there is much greater variation in the extent to which central banks are transparency about their decision making process, their internal forecasts, and their policy objectives.

But what is the point of being transparent? As noted earlier, Poole has articulated two goals of transparency: to meet the Fed's "responsibility to be politically accountable" and "to make monetary policy more effective." The next two subsections discuss each of these goals.

2.1 Transparency and accountability

The role transparency plays in supporting accountability can differ depending on whether the ultimate objectives of monetary policy are observable or unobservable. Consider first the case in which the objectives of monetary policy are, ex post, clearly measurable and observable. For concreteness, assume inflation is the only objective of the central bank and there is agreement on the appropriate measure of inflation that the central bank should control. In this environment, it is in principle straightforward to ensure

³See Eijffinger and Geraats (2006) and Dincer and Eichengreen (2007) for indexes of central bank transparency.

accountability. Observing the ex post rate of inflation would provide a simple means for judging the performance of the central bank. However, even under the conditions specified (a single measurable objective), simply observing the ex post realization of inflation is not sufficient to serve as an effective performance measure. The reason is that inflation is not directly controllable – even under an optimal policy (so that the central bank is doing exactly what it should be doing), the realized inflation rate can differ from the desired value. This difference may be small, but as long as there is any random variation that is beyond the ability of the central bank to eliminate, public accountability based solely on inflation outcomes will punish some good central bankers and reward some lucky ones.

Transparency can help promote accountability by allowing the public to base its evaluation of the central bank not just on observed inflation but on the information that was available to the central bank when it had to make its policy decision. Having access to internal bank forecasts, for example, allows outsiders to evaluate the decisions made by the central bank. This can mitigate some of the problems associated with evaluations based solely on realized inflation. Having access to the information on which decisions were based helps remove the influence of random uncontrollable events that affect inflation and therefore supports a better system of accountability.⁴

In general, however, policy objectives are not directly observable, and they may even be inherently unmeasurable. Certainly recent theoretical models, which have emphasized the use of the welfare of the representative agent as the appropriate objective of policy, have defined optimal policy in terms of unmeasurable objectives. It is not clear that we could reach agreement on the correct way to measure welfare, as that depends on the specific model we believe characterizes the economy, even if we could agree on how to define welfare. It certainly is not observable.

Transparency can be especially critical when objectives are unobserved. Assessing, or holding accountable, an economic agent when objectives are unobservable is not a situation unique to monetary policy and central banks. Perhaps the most prominent case in which public policy must deal with this situation is in the education field, where the objectives are high quality education and teaching but there exists wide disagreement over how to define and measure these qualities.

Since social welfare does depend on inflation, and inflation can be ob-

⁴As Tim Harford pointed out in a recent “Dear Economist” column (*Financial Times*, 9/1/2007), it might seem sensible for a company to judge its ice cream sales force on total sales, but having information about the weather allows for a better assessment of the contribution of the sales team to actual sales.

served, one might use inflation as a type of performance measure, holding the central bank accountable for achieving a low and stable inflation rate. Inflation targeting can be thought of as defining a performance measure for the central bank. The critical issue in choosing any performance measure, however, is how powerful one wants to make the incentives. If accountability is based strictly on realized inflation, and the consequences of missing the target are large, then the central bank will naturally focus on achieving the target even if this means sacrificing other, more difficult to measure, aspects of social welfare. The concern that inflation targeting produces too much of a focus on inflation control is at the heart of most criticisms of inflation targeting in the United States.

But this is where transparency becomes particularly important. Greater transparency can lessen the need to rely on a single easily measured performance indicator. When the public is able to assess the information about the economy on which the central bank based its policy decisions, it is no longer necessary to base accountability just on inflation outcomes. Less weight can be placed on inflation outcomes in evaluating the central bank (and holding it accountable) when there is greater transparency about what information the central bank had at the time it made its policy decisions (Walsh 1999).

2.2 Transparency and the effectiveness of monetary policy

Poole's second goal of transparency, promoting policy effectiveness, requires that private sector decisions be influenced, and influenced systematically, by the information central banks provide. With the development of new Keynesian models and their emphasis on the importance of forward-looking behavior, managing expectations to improve policy effectiveness has taken on a new importance. Woodford (2005) has gone so far as to state that "For not only do expectations about policy matter, but, at least under current conditions, very little *else* matters."⁵

The intuition for Woodford's statement is straightforward. Policy makers control directly only a short-term interest rate. Yet rational agents are forward looking and so base their spending and pricing decisions on their assessment of future interest rates, not just current rates. The recognition that expectations matter is not confined to academics; a recent article in the *Financial Times* states that "What really matters, both for the markets and the economy, is not the current policy rate but the expected path of

⁵Italics in the original.

future rates.”⁶

Transparency and its relationship to policy effectiveness played a key role in the large literature that focused on the average inflation rate bias that could arise under optimal discretionary policy. By and large, this literature emphasized political and operational transparency, and it employed models in which policy surprises were the source of the real effects of monetary policy. Geraats (2002) provides an excellent survey of the literature.

In these models, the central bank’s preferences were generally treated as stochastic and unknown. The policy instrument was also taken to be observed with error or subject to a control error. For example, the central bank might control nonborrowed reserves but this allowed only imperfect control of the money supply.⁷ Observing money growth would not provide enough information for the public to disentangle the effects of control errors from shifts in central bank preferences. Thus, there was opaqueness about political objectives and operational implementation. Transparency was typically modelled as a reduction in the noise in the signal on the policy instrument. The optimal degree of transparency balanced the gains from greater transparency in allowing the public to more quickly learn when the central bank’s preferences had shifted against the cost in terms of stabilization as the ability of the central bank to create surprises is reduced with greater transparency. Cukierman and Meltzer (1986) showed that the central bank may prefer to adopt a less efficient operating procedure than is technically feasible (i.e., not reduce the control error variance to its minimum possible level).⁸

As emphasized in recent discussions of transparency, however, new Keynesian models imply that it is predictable monetary policies, not surprises, that are most effective in achieving policy goals. In such an environment, transparency, rather than reducing the efficacy of policy, can actually increase it. Announcements about future policy actions, or about the central bank’s assessment of future economic developments, can affect private sector expectations of future interest rates, inflation, and economic activity. With spending and pricing decisions dependent on these expectations, using announcements to influence expectations gives the central bank an additional policy instrument. As such, it serves to make policy more effective. The

⁶ “Debate unfolds on likely impact of cut in US interest rates” by Krishna Guha, *Financial Times*, September 6, 2007, p. 2.

⁷ See, for example, Cukierman and Meltzer (1986) and Faust and Svensson (2002).

⁸ See also Faust and Svensson (2002) who show that, when the choice of transparency is made under commitment, patient central banks with small inflation biases will prefer minimum transparency. They argue that this result might account for the (then) relatively low degree of transparency that characterized the U.S. Federal Reserve.

argument that transparency can increase the effectiveness of monetary policy is certainly more consistent with the modern practice of central banks which has been uniformly to move in the direction of greater transparency.

But providing information to the public may have potential costs. These costs are associated with the conditional nature of any forecast. Some economists have worried that the public will not understand the distinction between a conditional and an unconditional forecast.⁹ Particularly when reputational considerations are important, deviating from a previously announced policy path may be interpreted as a deviation from a commitment equilibrium rather than as an appropriate response based on new information. If a central bank fails to raise interest rates after signalling that it planned to, private agents may believe the bank has become less concerned about inflation, causing inflation expectations to rise. Financial market participants may underestimate the conditionality of the announced rate path and so view deviations as introducing unwarranted uncertainty into financial markets. These factors may make the central bank reluctant to adjust rates, producing a lock-in effect that would reduce flexibility and limit policy effectiveness.

Even when the public understands the conditional nature of the guidance provided by the central bank, announcements may introduce new sources of volatility. The influential paper by Morris and Shin (2002) has highlighted one channel through which central bank announcements may have a detrimental effect. Unlike standard models which assume all private agents share the same information, Morris and Shin focus on the more realistic case of heterogeneous private information when each private agent must attempt to forecast what others are expecting.¹⁰ When private agents have individual sources of information, Morris and Shin have argued that there can be a cost to providing more accurate public information. Agents may overreact to public information, making the economy more sensitive to any forecast errors in the public information.

Subsequent research (e.g., Hellwig 2004, Svensson 2006) has suggested that the Morris-Shin result is not a general one and that better, more accurate, central bank information is welfare improving. However, just as the earlier literature on transparency employed models at odds with current policy frameworks (only surprises mattered, money supply was the instrument), the analysis of Morris and Shin is conducted within a framework

⁹Goodhart (2006).

¹⁰Woodford (2003) has investigated the role of higher order expectations in inducing persistent adjustments to monetary shocks in the Lucas-Phelps islands model. See also Hellwig (2002).

that fails to capture important aspects of actual monetary policy. For example, the issue facing most central banks is not whether to provide more accurate forecasts. Instead, the issue is whether or not to provide *more* information by, for example, announcing forecasts. And even in the absence of explicit announcements or guidance, central banks already provide information through the setting of the policy instrument. The impact of a change in the policy instrument will depend, in part, on the information that it conveys about the central bank's views of the economy.

The work by Morris and Shin has been extended by Amato and Shin (2003) who cast the Morris-Shin analysis in a more standard macro model. In their model, the central bank has perfect information about the underlying shocks. This ignores the uncertainty policy makers themselves face in assessing the state of the economy. Nor do Amato and Shin allow the private sector to use observations on the policy instrument to draw inferences about the central bank's information. They also assume one-period price setting and represent monetary policy by a price-level targeting rule. In Hellwig (2004), prices are flexible and policy is given by an exogenous stochastic supply of money; private and public information consists of signals on the nominal quantity of money.

The potential costs and benefits of releasing central bank forecasts have also been analyzed by Geraats (2005). However, Geraats assumes agents do not observe the bank's policy instrument prior to forming expectations and employs a traditional Lucas supply function. Her focus is on reputational equilibria in a two-period model with a stochastic inflation target. Thus, the model and the issues addressed differ from the focus on the role of information in a Morris-Shin-like environment.

Rudebusch and Williams (2006) and Gosselin, Lotz, and Wyplosz (2007) both focus specifically on the provision of future interest rate projections. Rudebusch and Williams explore the role of interest rate projections in a model of political transparency – the asymmetry of information pertains to policy preferences and the central bank's inflation target. Transparency is modeled as a reducing in the noise in the central bank's projection. In contrast to the model I develop in the next section, Rudebusch and William incorporate learning, finding that the public's ability to learn, and welfare, increase when interest rate projections are provided.

Gosselin, Lotz, and Wyplosz (2007) adopt a quite different approach and focus on what they characterize as creative opacity. In their model, the private sector learns from the information released by the central bank, but the central bank also learns about private sector information by observing long-term interest rates. By providing its projection for the short-term interest

rate, the central bank is able to recover private sector information from the long-term rate. This aligns expectations but may require the central bank to distort its current interest rate setting to achieve the desired long-term rate. If the central bank's information is poor, it may be better to remain opaque. While the role of central bank learning is a critical one, I ignore it in the model of section 3 in order to focus on the way the provision of information by the central bank affects inflation and output.

Thus, several questions remain unresolved concerning the role of transparency within the context of an environment in which agents have heterogeneous information and central bank actions and announcements constitute common information. Specially, how does the information conveyed by the central bank's instrument affect the central bank's incentives and alter the effectiveness of policy?¹¹ What is the effect of more information as opposed to better information? And are concerns about the added uncertainty of greater transparency warranted? These questions are addressed in the model of section 3.

3 Welfare effects of opaqueness and transparency

To investigate the role of economic transparency, I employ a simple model motivated by new Keynesian models based on Calvo-type pricing adjustment by monopolistic firms and by Morris and Shin's demonstration of the role asymmetric information can play.¹² Like Gosselin, Lotz, and Wyplosz, I assume the central bank's preferences are known. Unlike their model, however, I incorporate the common knowledge effect central to the Morris and Shin model. However, I focus on how private agents learn from the information provided by the central bank and ignore the reverse inference problem of the central bank inferring the private sector's information that is key to the model of Gosselin, Lotz, and Wyplosz.

The basic model is similar to the one employed in Walsh (2007a, 2007b). In this earlier work, only demand and cost shocks were present, so it was only necessary to make a single projection (of inflation or the output gap) to fully reveal the central bank's information (since the public also observed the policy instrument). The primary focus was also on partial transparency in the sense of Cornand and Heinmann (2006). The chief contributions

¹¹In Walsh (2007b), I show that this incentive effect under discretion can make it socially optimal to appoint a Rogoff-conservative central banker, that is, a central banker who places less weight on output gap stabilization than society does.

¹²As noted earlier, in the basic Morris-Shin model, Svensson (2006) shows that for almost all parameter values, better central bank information is welfare improving.

of the present paper are to enrich the information structure, to account fully for the welfare costs of relative price dispersion created by information heterogeneity, and to assess transparency in terms of both quantity (the role of providing more information) and quality (the effect of better information).

Firms receive private signals on the fundamentals shocks affecting the economy. Each period, a fraction of firms adjust their prices. In doing so, they care about their relative price and so must attempt to forecast what other price-adjusting firms are doing. But this requires the individual firm to predict what other firms are predicting about the shocks hitting the economy. Hence, higher order expectations will matter, as in Morris and Shin.

The central bank, like individual firms, is assumed to possess potentially noisy information on the economic outlook. I consider two policy regimes. In the first, the opaque regime and denoted by superscript o , the central bank makes no announcements. However, even in this regime, the central bank reveals something about its outlook for the economy when it sets its policy instrument. In the absence of other information, private agents combine the observation on the instrument with their own private information in forming expectations. A rise in the policy interest rate, for example, will be interpreted partially as reflecting the central bank's attempt to offset a projected positive demand shock and partially as a move to contract real output to offset a positive cost shock. When deciding on its policy, the central bank needs to take into account how the public will interpret its actions because the instrument conveys information.

The second regime corresponds to full transparency and is denoted by superscript f . In this regime, the central bank releases its projections on future economic developments. Since it is on this information that the central bank bases its policy decision, the actual setting of the instrument conveys no additional information. The benefits of this regime are that private sector forecasts are improved and, because there is more common information across firms, relative price dispersion is reduced. The potential costs is that private expectations react to what may turn out, ex post, to be central bank forecast errors.

While I assume the central bank operates in a discretionary manner in setting its policy instrument, I assume it can commit to a policy regime (opaque or transparent).

3.1 The basic model

The underlying model of price adjustment is based on Calvo, combined with the timing assumptions of Christiano, Eichenbaum, and Evans (2005) and the addition of firm-specific information. The Christiano, Eichenbaum, and Evans timing implies that firms who adjust their price for period t do so based on $t - 1$ information. Expressed alternatively, firms in period t make decisions about their prices for period $t + 1$. Because information differs across firms, price setting firms will not all set the same price as in the standard common information framework that is employed in most models. In addition, because firms care about their relative price, they must forecast the aggregate $t + 1$ price level when they set their individual price for that period. This also differs from standard specifications in which firms setting their price are assumed to know the aggregate equilibrium price level.

Three types of shocks are considered: 1) costs shocks that are assumed to represent inefficient volatility in real marginal costs; 2) aggregate demand shocks; and 3) shocks to the gap between the economy's flexible price equilibrium output and its efficient level of output. These latter will be referred to as welfare gap shocks. The model differs from standard new Keynesian models in that information is not common and firms must set prices before observing the current realizations of shocks.

The basic timing is as follow:

1. At the end of period t , the central bank forms projections about $t + 1$ economic conditions and sets its policy instrument θ_t .
2. Firms observe π_t , x_t , and θ_t as well as individual specific signals about $t + 1$ shocks. Firms may also observe announcements made by the central bank.
3. Those firms that can adjust their price set prices for $t + 1$.
4. Period $t + 1$ actual shocks occur and π_{t+1} and x_{t+1} are realized.

A randomly choose fraction $1 - \omega$ of firms optimally set their price for period $t + 1$. If β is the discount factor, one can show that (see Walsh 2007b)

$$\begin{aligned} \pi_{j,t+1}^* &= (1 - \omega)E_t^j \bar{\pi}_{t+1}^* + (1 - \omega\beta)\kappa E_t^j x_{t+1} \\ &\quad + (1 - \omega\beta)E_t^j e_{t+1}^s + \left(\frac{\omega\beta}{1 - \omega}\right) E_t^j \pi_{t+2}, \end{aligned} \quad (1)$$

where $\pi_{j,t+1}^*$ is the log price firm j sets for period $t+1$ relative to the period t average log price level (i.e., $p_{j,t+1}^* - p_t$), $E_t^j \bar{\pi}_{t+1}^*$ is firm j 's expectation about the average $\pi_{i,t+1}^*$ being set by other adjusting firms, $E_t^j x_{t+1}$ is firm j 's expectation about the output gap in $t+1$, e_{t+1}^s is the aggregate, common cost shock, and $E_t^j \pi_{t+2}$ is firm j 's expectation about future inflation. For simplicity, I assume (1) is linearized around a zero-inflation steady state.

To keep the model simple, I represent the demand side of the model in a very stylized, reduced form manner. Monetary policy is represented by the central bank's choice of θ_t and by any announcements the central bank might make. I assume θ_t is observed at the start of the period so that any firm that sets its price in period t can condition its choice on the central bank's policy action. The output gap is then equal to

$$x_{t+1} = \theta_t + e_{t+1}^v, \quad (2)$$

where e_{t+1}^v is a demand shock. While I will call θ_t the central bank's instrument, it essentially represents the central bank's intended output gap.

3.1.1 Information

As noted, there are three fundamental disturbances in the model: e_t^s representing cost factors that, for a given output gap and expectations of future inflation, generate inefficient inflation fluctuations; e_t^v , the aggregate demand disturbance; and e_t^u , a shock to the gap between the flexible-price output gap and the efficient output gap. I assume each is serially and mutually uncorrelated.

Firms in setting prices and the central bank in setting its policy instrument must act before learning the actual realizations of the aggregate shocks. Firm j 's idiosyncratic information $e_{j,t+1}^i$ for $i = s, v, u$ is related to the aggregate shock according to

$$e_{j,t+1}^i = e_{t+1}^i + \phi_{j,t+1}^i, \quad i = s, v, u.$$

The $\phi_{j,t+1}^i$ terms are identically and independently distributed across firms and time. These signals are private in the sense that they are unobserved by other agents. For convenience, each $\phi_{j,t+1}^i$ will be referred to as a noise term, even though $\phi_{j,t+1}^s$ is actually the idiosyncratic component of the firm's cost shock. All stochastic variables are assumed to be normally distributed. Define the signal to noise ratio $\gamma_j^i = \sigma_i^2 / (\sigma_i^2 + \sigma_{j,i}^2)$, where σ_i^2 is the variance

of e^i and $\sigma_{j,i}^2$ is the variance of ϕ_j^i . Let $\Omega_{j,t+1}$ denote the vector of private signals received by firm j , and let $\Omega_{t+1} = \int \Omega_{j,t+1}$ be the information aggregated over firms.

The central bank combines its information, models, and judgement to obtain forecasts of future economic disturbances. It will be convenient to represent this information, in parallel with the treatment of firm information, as signals on the three aggregate disturbances:

$$e_{cb,t}^i = e_{t+1}^i + \phi_{cb,t}^i, \quad i = s, v, u.$$

The noise terms ϕ_{cb}^i are assumed to be independently distributed and to be independent of ϕ_j^i for all i, j and t . Define $\gamma_{cb}^i = \sigma_i^2 / (\sigma_i^2 + \sigma_{i,cb}^2)$, where $\sigma_{i,cb}^2$ is the variance of ϕ_{cb}^i . Let $\Omega_{cb,t+1}$ denote the innovation to the central bank's information set. Let $Z_t' = [e_t^s \quad e_t^v \quad e_t^u]$. Then $E_t^{cb} Z_{t+1} = \Gamma_{cb} \Omega_{cb,t+1}$, where E^{cb} denotes expectations conditional on the central bank's information and

$$\Gamma_{cb} = \begin{bmatrix} \gamma_{cb}^s & 0 & 0 \\ 0 & \gamma_{cb}^v & 0 \\ 0 & 0 & \gamma_{cb}^u \end{bmatrix}.$$

The central bank's objective is to minimize, under discretion, a standard quadratic loss function that depends on inflation variability and output gap variability. Specifically, loss is given by

$$L_t^{cb} = E_t^{cb} \sum_{i=0}^{\infty} \beta^i [\pi_{t+i}^2 + \lambda_x (x_{t+i} - e_{t+i}^u)], \quad (3)$$

where e_t^u is equal to stochastic variation in the gap between the flexible-price output gap (x) and the welfare-maximizing output gap.

With staggered price adjustment, new Keynesian models imply that the welfare costs of inflation variability arise from the dispersion of relative prices it generates (Rotemberg and Woodford 1995, Woodford 2003a). Relative price dispersion can arise from inflation (because of staggered price adjustment) and because of informational asymmetries across firms. It can be shown (see the appendix) that the variance of relative prices across firms depends on π_t^2 and on the noise in the signals received by individual firms. Thus, social loss is given by

$$L_t^s = E_t \sum_{i=0}^{\infty} \beta^i [\pi_{t+i}^2 + \lambda_I z_{t+i}^2 + \lambda_x (x_{t+i} - e_{t+i}^u)], \quad (4)$$

where z_t^2 is relative price dispersion arising from asymmetric information across individual firms with the appropriate weight on this source of loss relative to π_t^2 given by

$$\lambda_I = \frac{(1 - \omega)^2}{\omega}.$$

The loss associated with information dispersion can be reduced if the central bank provides more information. However, this loss is not affected by the period-by-period policy choice the central bank makes in setting its instrument (conditional on the policy regime that defines the type of announcements the central bank makes). This, under discretion, the central bank takes the term z_t^2 in (4) due to informational dispersion as given and minimizes (3).

We can now evaluate equilibrium under each policy regime.

3.2 Equilibrium under the opaque regime

In regime o , firms observe their own private signals and the central bank's instrument. In regime f , the central bank provides its forecasts (equivalently, its signals) directly to the public.¹³ In the absence of central bank announcements, firm j 's new information is given by its private signals and the policy instrument. The new information available to firm j consists of $\Omega_{j,t+1}$ and θ_t . Assume beliefs about monetary policy are

$$\theta_t = \delta^o E_t^{cb} \psi_{t+1} = \delta^o \Gamma_{cb} \Omega_{cb,t+1},$$

where δ^o is 1×3 . These beliefs are consistent with a rational expectations equilibrium under discretionary monetary policy.

Define $\Theta^o = [\Theta_1^o \quad \Theta_2^o]$ such that Θ_1^o is 3×3 and Θ_2^o is 3×1 , where the ij^{th} element of Θ_1^o gives the effect of the firm's j^{th} signal on its forecast of the i^{th} shock. Similarly, the i^{th} element of Θ_2^o is the effect of θ_t on the firm's forecast of the i^{th} shock. Firm j 's expectation of Z_{t+1} is

$$E_t^j Z_{t+1} = \Theta_1^o \Omega_{j,t+1} + \Theta_2^o \theta_t.$$

Because the firm's signals on the different shocks are uncorrelated, Θ_1^o would, in the absence of the observation of θ_t , consist of a diagonal matrix with the signal to noise ratios along the diagonal. The off-diagonal elements of Θ_1^o can be non-zero when the firm combines its own information with θ_t to forecast

¹³ Alternatively, the central bank could announce its inflation and output gap forecasts; combined with the observed instrument setting, these announcements would fully reveal the central bank's signals.

the shocks. For example, suppose $\theta_t > 0$. This might indicate a response by the central bank to a negative demand shock, a negative cost shock, or a positive welfare gap shock. If the firm's signal on the demand shock is positive, then given θ_t , this makes it less likely the central bank is reacting to a negative demand shock. The firm will therefore alter its forecast of cost and target shocks.

The appendix shows that the equilibrium strategy for firm j will take the form

$$\pi_{j,t+1}^* = b_1^o \Omega_{j,t+1} + b_2^o \theta_t, \quad (5)$$

where b_1^o is 1×3 . Under both regimes, the expression for the coefficients on $\Omega_{j,t+1}$ in the firm's equilibrium strategy take the same form, and these are given in the appendix.¹⁴

The appendix shows that the impact of the instrument on an individual firm's pricing decision is

$$b_2^o = \left(\frac{1 - \omega\beta}{\omega} \right) \kappa + \left(\frac{1}{\omega} \right) [(1 - \omega)b_1^o + (1 - \omega\beta)(\iota_1 + \kappa\iota_2)] \Theta_2^o, \quad (6)$$

where ι_i is a 3×1 vector of zeros with a one in the i^{th} place. Equation (6) illustrates the channels through which a policy action affects the pricing decisions of firms. The first term, $(1 - \omega\beta)\kappa/\omega$ is the standard effect operating through the output gap. Since inflation is $(1 - \omega)$ times the pricing decision of the individual firm in a standard new Keynesian model, the effect on aggregate inflation operating through this terms would be $(1 - \omega)(1 - \omega\beta)\kappa/\omega$, which is the normal coefficient on the output gap in a new Keynesian model based on Calvo pricing.

The remaining terms on the right side in (6) represent the informational effects of policy actions. For example, observing θ_t affects the firm's expectations about cost, given by the term $(1 - \omega\beta)\iota_1\Theta_2^o$, and demand shocks, represented by the term $(1 - \omega\beta)\kappa\iota_2\Theta_2^o$. Observing θ_t also affects individual pricing decisions through the firm's expectations of what other firms are expecting, the $(1 - \omega)b_1^o$ term.

Equilibrium inflation is given by

$$\pi_{t+1} = (1 - \omega)\bar{\pi}_{t+1}^* = (1 - \omega)(b_1^o \Omega_{t+1} + b_2^o \theta_t) \quad (7)$$

and

$$\frac{\partial \pi_{t+1}}{\partial \theta_t} = (1 - \omega)b_2^o.$$

¹⁴Of course their values differ under the two regimes to the extent information available to firms differs.

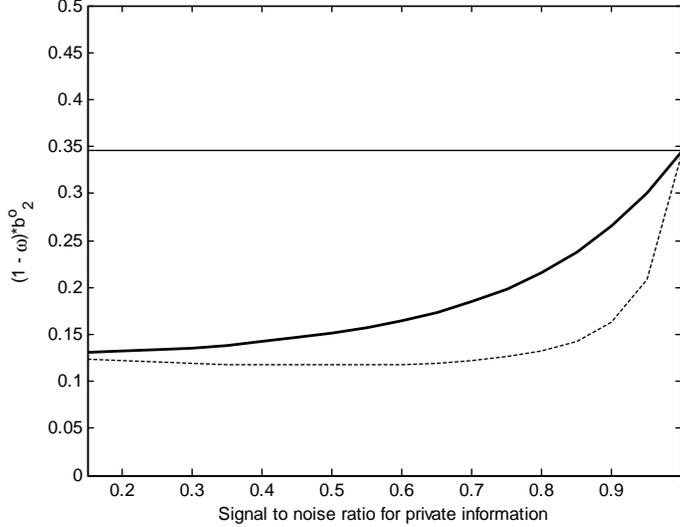

Figure 1: Elasticity of inflation with respect to the policy instrument in the opaque regime as a function of private information quality (solid line: $\gamma_{cb}^i = 0.5$; dotted line: $\gamma_{cb}^i = 0.9$).

The informational channels can significantly alter the impact of the central bank's instrument on inflation. I calibrate the model by setting $\omega = 0.65$ (as a compromise between micro evidence suggesting ω is on the order of 0.5 and time series estimates typically on the order of 0.8), $\beta = 0.99$, and $\kappa = 1.8$. These values imply $(1 - \omega)(1 - \omega\beta)\kappa/\omega = 0.3455$. The standard deviations of all shocks are set equal to one. Figure 1 shows how $(1 - \omega)b_2^o$ varies with the quality of private sector information, as measured by the signal to noise ratio γ_j^i . The horizontal line is drawn at 0.3455, the impact of θ on inflation in the absence of informational effects. When firms have perfect information on the shocks ($\gamma_j^i = 1$), the policy instrument conveys no information, and the effect of θ on inflation equals 0.3455.

However, when θ conveys information (i.e., when $\gamma_j^i < 1$), its impact on inflation is significantly reduced. Movements in θ are partially attributed to the central bank's response to the various shocks. A rise in θ , for example, lowers firms' forecasts of demand shocks. Since the net effect on the expected output gap is $\theta_t + E_t^j e_{t+1}^v$, the effect on price setting behavior and inflation is less than the change in θ . A rise in θ also leads firms to reduce their

forecast of cost shocks, partially offsetting the positive impact of a rise in θ on inflation. For a given quality of private sector information, the informational channel become more important as the central bank's information improves and private firms place more weight on the information conveyed by policy actions. The informational effects are larger, therefore, when the central bank has better quality information (compare the solid line in Figure 1 for $\gamma_{cb}^i = 0.5$ to the dashed line for $\gamma_{cb}^i = 0.9$).

Operating in a discretionary regime, the central bank sets policy optimally in each period based on its current forecasts about the future state of the economy. The first order condition for minimizing the expected value of the central bank's loss function (3) subject to (2) and (7) is given in the appendix. This first order condition can be solved for the optimal policy responses, and their values are also given in the appendix.

The solution to the model is obtained numerically by beginning with initial values for the policy coefficients, using these to obtain Θ^o , b_1^o , and b_2^o , and then obtaining new values for the policy coefficients. This process continues until convergence. Once the equilibrium values of b_1^o and b_2^o and the policy coefficients are obtained, aggregate inflation is given by

$$\pi_{t+1} = (1 - \omega) [(b_1^o + b_2^o \delta^o \Gamma_{cb}) \psi_{t+1} + b_2^o \delta^o \Gamma_{cb} \phi_{cb,t+1}],$$

while the welfare gap is

$$\begin{aligned} x_{t+1} - e_{t+1}^u &= \theta_t + e_{t+1}^v - e_{t+1}^u \\ &= \delta^o \Gamma_{cb} \Omega_{cb,t+1} + (\iota_2 - \iota_3) Z_{t+1} \\ &= (\delta^o \Gamma_{cb} + \iota_2 - \iota_3) Z_{t+1} + \delta^o \Gamma_{cb} \phi_{cb,t+1}. \end{aligned}$$

3.3 Equilibrium with full transparency

I interpret full transparency as a regime in which the central bank shares its information on the economy. Within the context of the model, this would mean that the central bank publishes its signals on the various disturbances so that $\Omega_{cb,t+1}$ becomes known to all firms. Equivalently, the central bank could publish its forecasts for inflation and the output gap. In a transparent regime, the instrument is no longer a source of information to the private sector. This alters the impact of θ_t on inflation and affects the central bank's incentives in setting policy. When the central bank provides its information to the public, the central bank's information set is a subset of the public's information set. In this context, Svensson and Woodford (2002) have shown that certainly equivalence holds with respect to the central bank's policy

problem. In particular, this implies that the optimal policy will be independent of the quality of either the central bank's information or the private sector's information.

Let $\Theta^f = \begin{bmatrix} \Theta_1^f & \Theta_2^f \end{bmatrix}$ be the appropriate 3×6 coefficient matrix such that

$$E_t^j Z_{t+1} = \Theta_1^f \Omega_{j,t+1} + \Theta_1^f \Omega_{cb,t+1}.$$

The appendix shows that the equilibrium strategy for price setting firms is

$$\pi_{j,t+1}^* = b_1^f \Omega_{j,t+1} + b_2^f \theta_t + b_3^f \Omega_{cb,t+1},$$

where b_1^f takes the same form as b_1^o (except with Θ_1^f replacing Θ_1^o in the expression for b_1^f , see the appendix). While the formula b_1^f is the same as for b_1^o , their values will differ as $\Theta^f \neq \Theta^o$. The effects of the central bank's instrument and information are given by

$$b_2^f = \frac{(1 - \omega\beta)}{\omega} \kappa$$

and

$$b_3^f = \left(\frac{1}{\omega}\right) \left[(1 - \omega)b_1^f + (1 - \omega\beta)(\iota_1 + \kappa\iota_2) \right] \Theta_2^f.$$

Inflation will equal $(1 - \omega)\bar{\pi}_{t+1}^*$, so

$$\frac{\partial \pi_{t+1}}{\partial \theta_t} = (1 - \omega)b_2^f = \frac{(1 - \omega)(1 - \omega\beta)\kappa}{\omega}$$

and is independent of any informational effects. The optimal policy coefficients for this case, giving the policy response to each signal, are given in the appendix.

4 The value of releasing information

We can now compare the effects of providing information by comparing outcomes under the opaque regime and the transparent regime. To assess outcomes under the two regimes, the model is solved using the same calibrated parameters as employed in section 3.2 (i.e., $\omega = 0.65$, $\beta = 0.99$, $\kappa = 1.8$). I initially set the variances of all shocks equal to 1. For the loss function, I set $\lambda_x = 1/16$, reflecting the use of quarterly inflation rates.

Table 1 shows the loss under each regime for different combinations of the signal to noise ratios for both the private sector and the central bank.

The first thing to note is the loss is increasing in the quality of private sector information (moving across rows from left to right) and decreasing in the quality of the central bank’s information (comparing the top panel to the bottom panel). Better private information makes expectations more sensitive to signals and so increases the volatility of expectations. Greater volatility of expectations produces more inflation volatility. This is welfare decreasing. Better central bank information is welfare improving because it allows the central bank to engage in more effective stabilization policies that reduce the volatility of inflation and the output welfare gap. While Morris and Shin (2002) suggest that improved common information could reduce welfare, the results in Table 1 are consistent with Hellwig (2004) and Svensson (2006) who argue that better quality central bank information generally improves welfare.

Table 1: Loss under alternative regimes ($\sigma_s^2 = \sigma_v^2 = \sigma_u^2 = 1$)

	γ_j^i				
$\gamma_{cb}^i = 0.5$	0.2	0.4	0.6	0.8	1.0
<i>opaque</i>	8.83	10.20	11.70	13.52	16.79
<i>transparent</i>	9.52	10.33	11.49	13.35	16.79
π equivalent	3.32	1.39	1.80	1.66	0
$\gamma_{cb}^i = 0.9$					
<i>opaque</i>	4.56	5.55	6.50	7.21	7.64
<i>transparent</i>	6.11	6.15	6.22	6.40	7.64
π equivalent	4.97	3.08	2.11	3.60	0

When $\gamma_j^i = 1$, firms observe the true shocks perfectly. In this case, the release of information or projections by the central bank is irrelevant and the loss is the same under both regimes, as shown in the last column of Table 1. When private information is imperfect, loss differs under the two regimes, and the regime with lowest loss is indicated in bold. The rows labelled “ π equivalent” express the reduction in loss under the optimal regime in terms of the reduction in average inflation (expressed at annual rates) that would yield a similar reduction in loss. For example, if $\gamma_j^i = 0.8$ and $\gamma_{cb}^i = 0.5$, the improvement of moving from an opaque regime to a transparent one is equivalent to a reduction in inflation of 1.66 percentage points. The general results are similar in both the top panel, when the central bank’s information is relatively poor (the signal and the noise have equal variances so that $\gamma_{cb}^i =$

0.5) and the bottom panel, when the central bank's information is relatively good ($\gamma_{cb}^i = 0.9$). What matters is the quality of private information. If this is low, then the expectations of firms (and what individual firms expect that other firms are expecting) are sensitive to any common information released by the central bank.

The results in Table 1 are robust to variations in the variances of the underlying shocks.¹⁵ The finding that transparency can lower welfare when private information is poor is suggestive of the Morris and Shin argument that noisy public information can decrease welfare. To investigate whether this is the effect that accounts for the relative performance of the two regimes, one can calculate the sources of loss under each regime. From (4), loss arises from inflation variability, welfare gap variability, and relative price dispersion due to information heterogeneity. Table 2 shows each of these components for the case $\gamma_{cb}^i = 0.9$ corresponding to the lower panel of Table 1 (results are similar for $\gamma_{cb}^i = 0.5$).

	$\gamma_{cb}^i = 0.9$				
	γ_j^i				
	0.2	0.4	0.6	0.8	1.0
<i>opaque</i>					
L	4.56	5.55	6.50	7.21	7.64
σ_π^2	1.82	2.15	2.85	3.72	3.22
$\lambda_x \sigma_{x-eu}^2$	1.68	1.71	1.84	2.20	4.42
$\lambda_I \sigma_z^2$	1.07	1.70	1.81	1.30	0
<i>transparent</i>					
L	6.11	6.15	6.22	6.40	7.64
σ_π^2	1.66	1.66	1.67	1.73	3.22
$\lambda_x \sigma_{x-eu}^2$	4.42	4.42	4.42	4.42	4.42
$\lambda_I \sigma_z^2$	0.02	0.06	0.13	0.26	0

Table 2 reveals three differences between the opaque equilibria and the transparent equilibria that are independent of the quality of private information. First, inflation is less volatile when policy is transparent. Second, the contribution of welfare gap volatility to the overall loss is much larger when policy is transparent. And third, the welfare cost of relative price

¹⁵For each σ_i^2 , its value was changed between 2 and 0.01 while the other variances were held fixed at 1.

dispersion is much smaller when policy is transparent. When γ_j^i is very low, opacity is the preferred regime because the welfare gap is much more stable. As will be discussed further below, the information channel of policy actions is large when private information quality is poor and this distorts the central bank's incentive such that policy reacts too little to cost shocks. This makes inflation more volatility but leaves the welfare gap more stable. Both inflation and output gap volatility in the opaque regime increase as γ_j^i rises, so that transparency becomes the preferred regime when private sector information is good.¹⁶

Table 3 shows the optimal policy responses to the central bank's three signals for γ_j^i equal to 0.4 and 0.8, and for γ_{cb}^i equal to 0.5 and 0.9. Response coefficients in the transparent regime are independent of the quality of both the private sector's and the central bank's information. This result follows from the demonstration by Svensson and Woodford (2002) that the central bank's decision problem satisfies the conditions for certainty equivalence if the private sector has more information than the central bank. This is the case in the transparent regime since private agents know both the central bank's signals and their own private signals. The way informational effects in the opaque regime distort stabilization policy is clear from the muted response (in absolute value) to signals on the cost shock and amplified response to signals on the welfare gap shock. The trade off between inflation and welfare gap volatility is clearly present – policy responds more to stabilize inflation under the transparent regime and, as a result, the welfare gap is more volatility, as was shown in Table 2.

In addition, transparency allows the central bank to more efficiently neutralize the effects of expected demand shocks. This can be seen by comparing the policy reaction coefficients under the two regimes. Under transparency, expected demand shocks are completely offset (i.e., $\delta^v = -1$) regardless of the quality of private sector or central bank information. Under the opaque regime, $\delta^v = -1$ only when private agents have perfect information on the shocks. Otherwise, δ^v is less than one in absolute value and demand shocks are not fully offset.

¹⁶ Also apparent in Table 2 is the result that the volatility of the welfare gap is independent of the quality of the private sector's information in the transparent regime. This reflects the certainty equivalence property of the central bank's problem in the transparent regime. The central bank's setting of its instrument is independent of γ_j^i and, as a result, so is the behavior of the output and welfare gaps.

Table 3: Optimal policy coefficients ($\sigma_s^2 = \sigma_v^2 = \sigma_u^2 = 1$)

	$\gamma_j^i = 0.4$			$\gamma_j^i = 0.8$		
	δ^s	δ^v	δ^u	δ^s	δ^v	δ^u
$\gamma_{cb}^i = 0.5$						
<i>opaque</i>	-0.0947	-0.8884	0.7179	-0.2510	-0.9764	0.5246
<i>transparent</i>	-0.3647	-1.0000	0.3436	-0.3647	-1.0000	0.3436
$\gamma_{cb}^i = 0.9$						
<i>opaque</i>	-0.0816	-0.8944	0.7475	-0.1865	-0.9713	0.6356
<i>transparent</i>	-0.3647	-1.0000	0.3436	-0.3647	-1.0000	0.3436

Under the opaque regime, the public will confuse movements in the instrument designed to offset forecasted demand shocks with movements associated with responds to either cost or welfare gap shocks. As a consequence, instrument moves aimed at offsetting demand shocks can affect inflation expectations and cause actual inflation to fluctuate as the public attributes part of the instrument change to these other shocks. This makes it optimal to not offset demand shocks completely. Once the public can infer the central bank's estimate of demand shocks, as it can under transparency, there is no longer any reason not to fully react to insulate the output gap and inflation from projected demand shocks, so $\delta_2^v = -1$.

In new Keynesian models, the welfare costs of inflation are due to the relative price dispersion that arises with staggered price adjustment. Heterogeneity in the information available to individual firms will also create relative price dispersion. Since information provided by the central bank is common information, it can help reduce relative price dispersion. Figure 2 shows the measure of relative price dispersion due to asymmetric information as a function of the quality of private sector information. The solid line with asterisks corresponds to the case of poor quality central bank information ($\gamma_{cb}^i = 0.5$) under the opaque regime, and the unconnected asterisks correspond to the opaque regime with high quality central bank information ($\gamma_{cb}^i = 0.9$). The diamonds indicate the outcomes under the transparent regime with low quality central bank information (the solid line) and high quality central bank information (the unconnected diamonds).

When $\gamma_j^i = 1$, all firms share the same information, so dispersion due to heterogeneous information goes to zero under either policy regime. However, relative price dispersion is increasing in γ_j^i for low values of γ_j^i . When firms have very poor quality information, the level of informational heterogeneity is high, but because the information is of low quality, firms do not respond strongly to it. As information quality improves, firms react more strongly

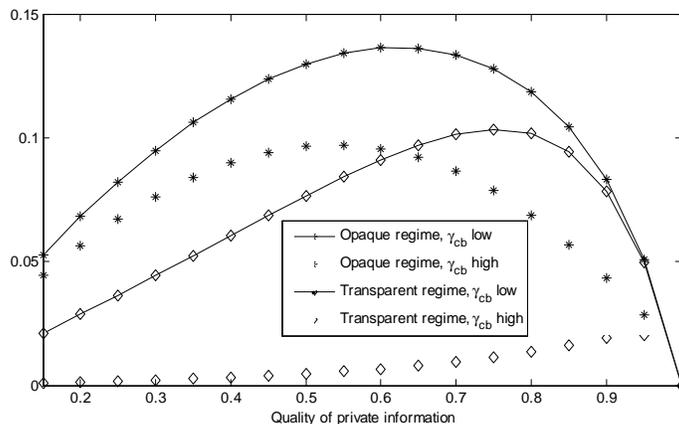

Figure 2: Relative price dispersion due to heterogeneous information

to their own private information and this increases the dispersion of prices.

Now consider the role of the quality of the central bank’s information under the opaque regime. Relative price dispersion is lower when the central bank’s information is good than when it is poor, though the loss from relative price dispersion actually constitutes a larger fraction of total social loss when the central bank’s information is good. This is due to the better stabilization the central bank can achieve when it has better information on the economy. Not surprisingly, relative price dispersion is always lower under the corresponding transparency regime. For the same reason, better central bank information reduces relative price dispersion under the transparency regime.

5 Conclusions

When the private sector and the central bank do not share the same information, policy actions become a source of information to the public. Policy has both direct effects on the output gap and indirect effects through the information conveyed by the central bank’s actions. Under an opaque policy regime, however, certainty equivalence does not hold, and informational channels affect the incentives faced by the central bank. Optimal policy will depend on the quality of both the central bank’s information and the public’s information. The central bank stabilizes inflation less and the welfare gap more than would occur in a transparent policy regime.

Under complete transparency, private agents have access to the central bank's assessment of the economy. In this case, policy actions no longer provide any additional information and the policy problem satisfies a form of certainty equivalence (Svensson and Woodford 2002). Optimal policy is independent of the quality of the central bank's information.

Consistent with the work of Svensson (2006) and Hellwig (2004), better central bank information was found to improve welfare. With better information, the central bank can implement more effective stabilization policies. The effect of providing more information by making announcements about projected inflation and the output gap is more ambiguous. Transparency always acts to lower relative price dispersion across firms by expanding the set of common information, but central bank announcements can make expectations more volatile, particularly if firms have relatively poor information. Transparency dominates opacity when the private sector has relatively good information, since in this case firms do not overreact to the information contained in the central bank's announcements. However, if private sector information is poor, central bank announcements can reduce welfare. So while *better* central bank information is desirable, *more* central bank information may not be.

Appendix

Welfare weight on information dispersion: The welfare loss in new Keynesian models arises from the inefficient dispersion of prices across firms. Let $p_{j,t}$ denote firm j 's price and let \bar{P}_t be the aggregate price level. Then

$$\begin{aligned}\Delta_t &\equiv \text{var}_j (\log p_{j,t} - \bar{P}_{t-1}) \\ &= E_t (\log p_{j,t} - \bar{P}_{t-1})^2 - (E_t \log p_{j,t} - \bar{P}_{t-1})^2 \\ &= E_t (\log p_{j,t} - \bar{P}_{t-1})^2 - (\bar{P}_t - \bar{P}_{t-1})^2.\end{aligned}$$

Using the assumptions of the Calvo model, the first term on the right can be written as

$$\omega E (\log p_{j,t-1} - \bar{P}_{t-1})^2 + (1-\omega) E_t (\log p_{j,t}^* - \bar{P}_{t-1})^2 = \omega \Delta_{t-1} + (1-\omega) E_t (\log p_{j,t}^* - \bar{P}_{t-1})^2.$$

Now

$$\log p_{j,t}^* - \bar{P}_{t-1} = \log p_{j,t}^* - \log \bar{p}_t^* + \log \bar{p}_t^* - \bar{P}_{t-1},$$

where the first term on the right is zero in the standard new Keynesian model with common information across firms. Hence,

$$E_t (\log p_{j,t}^* - \bar{P}_{t-1})^2 = E_t (\log p_{j,t}^* - \log \bar{p}_t^*)^2 + (\log \bar{p}_t^* - \bar{P}_{t-1})^2$$

since the idiosyncratic noise is independence of the fundamental shocks. From the definition of inflation,

$$\pi_t = (1 - \omega) (\log \bar{p}_t^* - \bar{P}_{t-1}),$$

so

$$E_t (\log p_{j,t}^* - \bar{P}_{t-1})^2 = E_t (\log p_{j,t}^* - \log \bar{p}_t^*)^2 + \left(\frac{1}{1 - \omega} \right)^2 \pi_t^2.$$

Combining these results,

$$\begin{aligned}\Delta_t &= \omega \Delta_{t-1} + (1 - \omega) E_t (\log p_{j,t}^* - \log \bar{p}_t^*)^2 + \left(\frac{1}{1 - \omega} \right)^2 \pi_t^2 - \pi_t^2 \\ &= \omega \Delta_{t-1} + (1 - \omega) E_t (\log p_{j,t}^* - \log \bar{p}_t^*)^2 + \left(\frac{\omega}{1 - \omega} \right)^2 \pi_t^2.\end{aligned}$$

It follows that

$$E_t \sum_{i=0}^{\infty} \beta^i \Delta_{t+i} = \left(\frac{\omega}{1 - \omega} \right) \left(\frac{1}{1 - \omega \beta} \right) E_t \sum_{i=0}^{\infty} \beta^i [\pi_{t+i}^2 + \lambda_I (\log p_{j,t+i}^* - \log \bar{p}_{t+i}^*)],$$

where $\lambda_I = (1 - \omega)^2/\omega$.

The opaque regime: Let

$$\Sigma = \begin{bmatrix} \sigma_s^2 & 0 & 0 \\ 0 & \sigma_v^2 & 0 \\ 0 & 0 & \sigma_u^2 \end{bmatrix},$$

$$\Sigma_j = \begin{bmatrix} \sigma_s^2 + \sigma_{j,s}^2 & 0 & 0 \\ 0 & \sigma_v^2 + \sigma_{j,v}^2 & 0 \\ 0 & 0 & \sigma_u^2 + \sigma_{j,u}^2 \end{bmatrix},$$

and

$$\Sigma_{cb} = \begin{bmatrix} \sigma_s^2 + \sigma_{cb,s}^2 & 0 & 0 \\ 0 & \sigma_v^2 + \sigma_{cb,v}^2 & 0 \\ 0 & 0 & \sigma_u^2 + \sigma_{cb,u}^2 \end{bmatrix}.$$

In the absence of central bank announcements, firm j 's new information is given by

$$\begin{bmatrix} e_{t+1}^s + \phi_{j,t+1}^s \\ e_{t+1}^v + \phi_{j,t+1}^v \\ e_{t+1}^u + \phi_{j,t+1}^u \\ \theta_t \end{bmatrix} = \begin{bmatrix} \Omega_{j,t+1} \\ \theta_t \end{bmatrix},$$

where $\theta_t = \delta^o \Gamma_{cb} \Omega_{cb,t+1}$. Define

$$\begin{aligned} \Theta^o &= \begin{bmatrix} \Sigma & \Sigma \Gamma'_{cb} \delta^{o'} \end{bmatrix} \begin{bmatrix} \Sigma_j & \Sigma \Gamma'_{cb} \delta^{o'} \\ \delta^o \Gamma_{cb} \Sigma & \delta^o \Gamma_{cb} \Sigma_{cb} \Gamma'_{cb} \delta^{o'} \end{bmatrix}^{-1} \\ &= \begin{bmatrix} \Theta_1^o & \Theta_2^o \end{bmatrix}, \end{aligned}$$

where Θ_1^o is 3×3 and Θ_2^o is 3×1 . Thus, firm j 's expectation of Z_{t+1} is

$$\begin{aligned} E_t^j Z_{t+1} &= \Theta_1^o \Omega_{j,t+1} + \Theta_2^o \theta_t \\ &= \Theta_1^o \Omega_{j,t+1} + \Theta_2^o \delta^o \Gamma_{cb} \Omega_{cb,t+1}. \end{aligned}$$

The aggregate information (i.e., aggregated over all firms) is

$$\begin{bmatrix} \Omega_{t+1} \\ \theta_t \end{bmatrix} = \begin{bmatrix} e_{t+1}^s \\ e_{t+1}^v \\ e_{t+1}^u \\ \theta_t \end{bmatrix} = \begin{bmatrix} Z_{t+1} \\ \theta_t \end{bmatrix}.$$

Defining ι_i as a 1×3 vector with a 1 in the i^{th} place and zeros elsewhere, we can write (1), a price-adjusting firm's price change, as

$$\begin{aligned}\pi_{j,t+1}^* &= (1 - \omega)E_t^j \bar{\pi}_{t+1}^* + (1 - \omega\beta)\kappa\theta_t + (1 - \omega\beta)(\iota_1 + \kappa\iota_2)E_t^j Z_{t+1} + \left(\frac{\omega\beta}{1 - \omega}\right)E_t^j \pi_{t+2} \\ &= (1 - \omega)E_t^j \bar{\pi}_{t+1}^* + (1 - \omega\beta)\kappa\theta_t \\ &\quad + (1 - \omega\beta)(\iota_1 + \kappa\iota_2)(\Theta_1^o \Omega_{j,t+1} + \Theta_2^o \theta_t) + \left(\frac{\omega\beta}{1 - \omega}\right)E_t^j \pi_{t+2}.\end{aligned}$$

An equilibrium strategy for firm j will take the form

$$\pi_{j,t+1}^* = b_1^o \Omega_{j,t+1} + b_2^o \theta_t,$$

where b_1^o is 1×3 .

In forming expectations about the pricing behavior of other firms adjusting in the current period, firm j 's expectation of $\bar{\pi}_{t+1}^*$ is given by

$$\begin{aligned}E_t^j \bar{\pi}_{t+1}^* &= b_1^o E_{t+1}^j \Omega_{t+1} + b_2^o \theta_t \\ &= b_1^o E_{t+1}^j Z_{t+1} + b_2^o \theta_t \\ &= b_1^o [\Theta_1^o \Omega_{j,t+1} + \Theta_2^o \theta_t] + b_2^o \theta_t \\ &= b_1^o \Theta_1^o \Omega_{j,t+1} + (b_1^o \Theta_2^o + b_2^o) \theta_t.\end{aligned}$$

Since

$$\pi_{t+1} = (1 - \omega)\bar{\pi}_{t+1}^*,$$

it follows that

$$\begin{aligned}E_t^j \pi_{t+2} &= (1 - \omega)E_t^j \bar{\pi}_{t+2}^* \\ &= (1 - \omega)E_t^j [b_1^o \Theta_1^o \Omega_{j,t+2} + (b_1^o \Theta_2^o + b_2^o) \theta_{t+1}] \\ &= 0.\end{aligned}$$

Substituting these into the equation for $\pi_{j,t+1}^*$ and collecting terms,

$$\begin{aligned}\pi_{j,t+1}^* &= (1 - \omega)b_1^o \Theta_1^o \Omega_{j,t+1} + (1 - \omega\beta)(\iota_1 + \kappa\iota_2)\Theta_1^o \Omega_{j,t+1} \\ &\quad + (1 - \omega\beta)\kappa\theta_t + (1 - \omega)(b_1^o \Theta_2^o + b_2^o)\theta_t \\ &\quad + (1 - \omega\beta)(\iota_1 + \kappa\iota_2)\Theta_2^o \theta_t.\end{aligned}$$

Equating coefficients with the proposed solution yields

$$b_1^o = [(1 - \omega\beta)(\iota_1 + \kappa\iota_2)]\Theta_1^o [I_3 - (1 - \omega)\Theta_1^o]^{-1}.$$

The expression for b_2^o is reported in the text.

The objective function under discretion involves minimizing

$$E_t^{cb} \left[\pi_{t+1}^2 + \lambda_x (x_{t+i} - e_{t+1}^u)^2 \right]$$

subject to (2) and (7). The first order condition for the central bank decision problem under discretion is

$$(1 - \omega) b_\theta E_t^{cb} \pi_{t+1} + \lambda_x \left(\theta_t + E_t^{cb} e_{t+1}^v - E_t^{cb} e_{t+1}^u \right) = 0.$$

From (7),

$$\begin{aligned} E_t^{cb} \pi_{t+1} &= (1 - \omega) b_1^o E_t^{cb} \Omega_{j,t+1} + (1 - \omega) b_2^o \theta_t \\ &= (1 - \omega) b_1^o \Gamma_{cb} \Omega_{cb,t+1} + (1 - \omega) b_2^o \theta_t \end{aligned}$$

since

$$E_t^{cb} \Omega_{j,t+1} = E_t^{cb} Z_{t+1} = \Gamma_{cb} \Omega_{cb,t+1}.$$

Hence, the first order condition becomes

$$\begin{aligned} \left[\lambda_x + (1 - \omega)^2 (b_2^o)^2 \right] \theta_t &= (1 - \omega) b_2^o E_t^{cb} e_{t+1}^u \\ &\quad - (1 - \omega)^2 b_2^o b_1^o \Gamma_{cb} \Omega_{cb,t+1} - \lambda_x E_t^{cb} e_{t+1}^v. \end{aligned}$$

This in turn implies that

$$\begin{aligned} \left[\lambda_x + (1 - \omega)^2 (b_2^o)^2 \right] \theta_t &= -(1 - \omega)^2 b_2^o b_1^o \Gamma_{cb} \Omega_{cb,t+1} \\ &\quad + \left[0 \quad -\lambda_x \quad (1 - \omega) b_2^o \right] \Gamma_{cb} \Omega_{cb,t+1}. \end{aligned}$$

Hence,

$$\theta_t = \delta^o \Gamma_{cb} \Omega_{cb,t+1},$$

where $\delta^o = \left[\delta^s \quad \delta^v \quad \delta^u \right]$ and

$$\delta^s = - \left[\frac{(1 - \omega)^2 b_2^o b_{11}^o}{\lambda_x + (1 - \omega)^2 (b_2^o)^2} \right] \quad (8)$$

$$\delta^v = - \left[\frac{\lambda_x + (1 - \omega)^2 b_2^o b_{12}^o}{\lambda_x + (1 - \omega)^2 (b_2^o)^2} \right] \quad (9)$$

$$\delta^u = \left[\frac{\lambda_x - (1 - \omega)^2 b_2^o b_{13}^o}{\lambda_x + (1 - \omega)^2 (b_2^o)^2} \right].$$

Full transparency: In regime f , the central bank announces its signals so that firms observe $\Omega_{cb,t+1}$ directly. Firms' expectations now depend on $\Omega_{cb,t+1}$ and not directly on θ_t .

Guess an equilibrium strategy of the form

$$\pi_{j,t+1}^* = b_1^f \Omega_{j,t+1} + b_2^f \Omega_{cb,t+1} + b_3^f \theta_t.$$

Then following the same procedures as used to solve the model without announcements, one finds that

$$\begin{aligned} b_1^f &= [(1 - \omega\beta)(\iota_1 + \kappa\iota_2)] \Theta_1^f \left[I_3 - (1 - \omega)\Theta_1^f \right]^{-1} \\ b_2^f &= \left(\frac{1}{\omega} \right) \left[(1 - \omega)b^f + (1 - \omega\beta)(\iota_1 + \kappa\iota_2) \right] \Theta_2^f. \\ b_3^f &= \frac{(1 - \omega\beta)}{\omega} \kappa. \end{aligned}$$

Optimal policy in this regime satisfies the first order condition

$$(1 - \omega)b_3^f E_t^{cb} \pi_{t+1} + \lambda_x \left(\theta_t + E_t^{cb} e_{t+1}^v - E_t^{cb} e_{t+1}^u \right) = 0.$$

Note that

$$E_t^{cb} \pi_{t+1} = (1 - \omega) \left[\left(b_1^f \Gamma_{cb} + b_2^f \right) \Omega_{cb,t+1} + b_3^f \theta_t \right]$$

since $E_t^{cb} \Omega_{j,t+1} = \Gamma_{cb} \Omega_{cb,t+1}$. Solving the first order condition yields

$$\theta_t = d^f \Gamma_{cb} \Omega_{cb,t+1},$$

with $d^f = [d^s \quad d^v \quad d^u]$ and

$$\begin{aligned} d^s &= -(1 - \omega)^2 b_3^f \left[\frac{(b_{21}^f / \gamma_{cb}^s) + b_{11}^f}{\lambda_x + (h^f)^2 (1 - \omega)^2} \right] \\ d^v &= - \left[\frac{\lambda_x + (1 - \omega)^2 b_3^f \left[(b_{22}^f / \gamma_{cb}^v) + b_{12}^f \right]}{\lambda_x + (b_3^f)^2 (1 - \omega)^2} \right] \\ d^u &= \left[\frac{\lambda_x - (1 - \omega)^2 b_3^f \left[(b_{23}^f / \gamma_{cb}^u) + b_{13}^f \right]}{\lambda_x + (b_3^f)^2 (1 - \omega)^2} \right]. \end{aligned}$$
