

Ex. a swap() fn. that doesn't work

```
def swap(x, y):
```

```
    temp = x
```

```
    x = y
```

```
    y = temp
```

```
#end swap()
```

```
in main()
```

```
    a = 4
```

```
    b = 5
```

```
    print(a, b) # 4 5
```

```
    swap(a, b)
```

```
    print(a, b) # 4 5
```

Picture of memory :-

we can do an effective swap  
by using lists .

Ex. Swap. Py

we can turn a range obj. into a list obj

`list(range(5))` # [0, 1, 2, 3, 4]

| 0 | 1 | 2 | 3 | 4 |
|---|---|---|---|---|
| 0 | 1 | 2 | 3 | 4 |

why have range objects?

Ex. for x in range(10000000):  
 Pass

for x in list(range(10000000)):  
 Pass

Variations on range():

range(stop) start=0, step=+1

range(start, stop) step=+1

range(start, stop, step)

Ex.

$\text{range}(3, 10) \neq [3, 4, 5, 6, 7, 8, 9]$

$\text{range}(10, 3) \neq []$  empty

$\text{range}(3, 10, 2) \neq [3, 5, 7, 9]$

$\text{range}(3, 11, 2) \neq [3, 5, 7, 9]$

$\text{range}(10, 3, -1) \neq [10, 9, 8, 7, 6, 5, 4]$

$\text{range}(10, 3, -2) \neq [10, 8, 6, 4]$

outer loop  
Iteration

Ex. Bubble Sort. Py

• while loop :

while cond :

loop repetition condition (LRC)

Two equiv loops :

```
for k in range(1, n):
    do something
#end
```

after  
→ Print(k)  
# k = n - 1

```
k = 1
while k < n:
    do something
    k += 1
#end
```

after  
→ Print(k)  
# k = n
