

CSE 20 4-30-20

Extend Pa4 by 1 day

Exercise

figure out how to swap ints
 $x \neq y$ without a temp.

Ex. BetterSort.py

Instance

<u>x</u>	<u>y</u>	<u>z</u>
3	1	2
		
1	3	2
		
1	2	3

last comp. of
 $x \neq y$ was
unnecessary

Instance

<u>x</u>	<u>y</u>	<u>z</u>
3	2	1
2	3	1
2	1	3
1	2	3

last comp.
of $x \neq y$
was necessary

Ex. Sort4.py

Instance	<u>a</u>	<u>b</u>	<u>c</u>	<u>d</u>
	4	3	2	1
	3	4	2	1
	3	2	4	1
	3	2	1	4
	2	3	1	4
	2	1	3	4
	1	2	3	4

chap 6: more on functions

Ex write a function that returns the absolute value of a number

$$|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$$

Possible solution: (bad solution)

```
def f(x):
    if x < 0:
        return -x
    elif x > 0:
        return x
    # end f()
```

Exercise:

fix this!!

if $x = 0$, return None

Ex. words.py

Exercise

write a function ~~called~~ with
heading

```
def count_2_letter_words(L):
```

```
    ...
```

```
end ...
```

that counts and returns the
number of 2-letter words in
a list of strings L.

chap 7. more on loops

Recall Python's List object

`L = ['one', 'two', 'three']`

`L = [1, 2, 3]`

`L = ['one', 2, 3.0]`

Ex. how not to swap two values.

```
def swap(x, y):  
    temp = x  
    x = y  
    y = temp  
#end swap()
```

why doesn't swap work?

memory picture:

main

a
4

b
5

a b ← arguments
swap(x, y)

x
4 5

y
~~5~~ 4

temp
4

when `swap(a, b)` is called, a is copied to x, and b is copied to y. The copies are swapped by

$$\left\{ \begin{array}{l} \text{temp} = x \\ x = y \\ y = \text{temp} \end{array} \right.$$

when `swap()` returns, the originals, a and b are unchanged.

□

A list can be used to create an effective swap function.

```
def swap(L, i, j):
```

```
    temp = L[i]
```

```
    L[i] = L[j]
```

```
    L[j] = temp
```

```
#end swap()
```

Now in main -----

```
A = [1, 4, 3, 5, 7]
```

```
swap(A, 1, 3)
```

```
print(A)
```

Output : [1, 5, 3, 4, 7]

swapped.

How do List variable work?

$A = [1, 4, 3, 5, 7]$

Picture of memory:

Now DO

$B = A$

We have not created a new List object. Instead we have 2 List reference variables storing the address of the same List Object.

Picture

Try this:

`B[2] = 9`

`print(A[2])` # output 9, not 3

The reference variable `B` can now be used to alter the values in the list object.

`print(A)` # output: `[1, 4, 9, 5, 7]`

why did the new swap() work?
look at memory:

main

arguments

A 1 3

↓ ↓ ↓

swap(L, i, j)

L [] i [1] j [3] temp [4]

the body of swap() now changes values in
list A !!

temp = L[i]

L[i] = L[j]

L[j] = temp
