

CSE 20

Beginning Programming in Python

Programming Assignment 4

In this assignment you will write a Python program that plays an interactive guessing game with the user. Your program will generate a random integer in the range 1 to 10, then allow the user three guesses to determine the integer. After each guess your program will inform the user whether the guess was correct, too high, or too low. Your source file for this project will be called `Guess.py`. Here is a transcript of several plays of the game. The `$` symbol stands for the command line prompt and is not typed by the user.

```
$ python3 Guess.py

I'm thinking of an integer in the range 1 to 10. You have three guesses.

Enter your first guess: 5
Your guess is too low.

Enter your second guess: 7
Your guess is too low.

Enter your third guess: 9
You win!

$ python3 Guess.py

I'm thinking of an integer in the range 1 to 10. You have three guesses.

Enter your first guess: 3
Your guess is too low.

Enter your second guess: 8
Your guess is too high.

Enter your third guess: 5
Your guess is too low.

You lose. The number was 6.

$ python3 Guess.py

I'm thinking of an integer in the range 1 to 10. You have three guesses.

Enter your first guess: 4
Your guess is too low.

Enter your second guess: 7
Your guess is too high.

Enter your third guess: 6
You win!

$
```

Observe that there are blank lines at the beginning and end of program output, and blank lines separating guesses. Your program should match the above format exactly.

This is a very new kind of project for us, in which the program must adapt to user input. Use conditional statements (`if` and `if-else`, `if-elif-else`) to control your program's behavior. These control structures are discussed in Chapter 5 of the text (beginning on p. 61 of the pdf version), and will be covered at length in class.

Use the `random` module, and its `randint()` method to generate the random number. You can read about this module and its methods at

<https://docs.python.org/3/library/random.html?highlight=random#module-random>

Once the mystery number is chosen, program operation will depend on user input. This is where the conditional operations come in. Your program must give truthful responses to the user's guesses then halt when either the right number is guessed, or the user runs out of guesses.

What to turn in

Submit your program `Guess.py`, to the assignment name `pa4` before the due date. As always start early and ask questions in office hours and on piazza.

Discussion

Although this game is very simple, it is interesting to consider what strategy the user might adopt. Try to verify for yourself that if we were to allow four guesses instead of three, then a strategy exists that would find the mystery number with certainty, i.e. the guesser could always win. Similarly if we were to restrict the number to the set $\{1, 2, 3, 4, 5, 6, 7\}$, then it can always be found in three guesses. The game, as defined above, does possess an optimal strategy (optimal in the sense that it maximizes the probability winning.) Try to deduce such a strategy, and show that by using it, the guesser will win 70% of the time. As an exercise, write a program that plays the other side of the game (i.e. the role of guesser) and that implements this optimal strategy. This exercise will yield no credit for the current assignment, but it may form the basis of some future (more difficult) project.
