# Chemers, Hu, & Garcia (2001), Figure 2.

Comments/Questions

- Is this a "true" path model? Why or why not?
- How many exogenous vars? Endogenous?
- Can you compute: observations, parameters, df?
- Which endogeous variable has the most of its variance explained? The least?
- Can you confirm the size of the standardized mediated effect of self-efficacy on academic expectations ($\beta = .08$)?
- Would it be possible to replicate this analysis, using just the information in the article?
- Why are there no covariances in this model?

Suggestions

- Clarify which variables were T1 and which were T2 measures (mentioned in discussion but not earlier?)
- Give χ2 and df
- Check use of the word "moderation" (should say "mediation" instead; no interactions were tested in this model)
- Test alternative models?
  - e.g., one with direct effects to stress, health, and adjustment?
